Design Guidance

1. The above ground drainage and sanitation systems should comply with the current editions of the following guidelines and regulations:
   - The Building Regulations Part H.
   - BS EN 12056 Gravity Drainage systems inside buildings BS EN 752 below ground drainage.
   - Water Regulations.
   - Institute of Plumbing and Heating Engineers – Plumbing and Engineering Services Design Guide.
   - Legionella Code of Practice and guidance documentation.

2. Fully ventilated systems shall be employed. Air admittance valve should not be used.

3. All toilets and plant rooms should include provision for floor drains with deep traps.

4. No above ground drainage shall pass through lift shafts; lift motor rooms, electrical switch rooms or computer server rooms.

5. All laboratory waste systems must be designed to withstand attack from chemicals and acid (e.g. polypropylene). They are to be kept separate from other systems to the point of entry into the underground drainage. Anti-siphon bottle traps to be fitted to all sinks. In certain circumstances Acid Neutralisation / Dilution Tanks shall be utilised where corrosive liquids / spent acids or harmful chemicals which can cause damage to main sewer drainage or are likely to create noxious or toxic fumes or interfere with sewage treatment processes.

6. Careful consideration must be given to the choice of materials used for above and below ground drainage systems, taking into account foundations of buildings, fluid contents, the risk of noise break out and the risk of fire damage.

7. Grease management to all hot food catering facilities shall be by installing grease removal machines from pre-rinse and pot wash sinks and combi-ovens. No bio-systems shall be used. External Grease Traps / interceptors shall also be employed wherever feasible and practical.

8. All above ground drainage designs shall be provided with suitable accessible rodding facilities including all transitions between above and below ground drainage services at the lowest most outlet on each stack.

9. Suspended drainage runs shall be kept as straight as practical from A to B without deviation.

10. All changes of direction shall be made with either long radius bends or 45° bends.

11. Suspended pipework to be arranged such that rodding access points are not required and that rodding of the pipework can be carried out safely from the floor level above the offset.

12. All rodding access points are to be installed on pipework above the flood levels of the sanitary appliances discharging into them.

13. Branch pipework that is discharging into a suspended main drain must be made with a 45° branch swept in the direction of the flow.

14. Rodding access must always be provided on all pipes prior to discharge into the underground drainage system.

15. Sufficient access doors shall be provided to enable all pipework to be tested and maintained effectively.

16. Wet floor showers to be provided with a good quality shower drain that incorporates a removable trap and sediment bucket and be suitable to receive the type of floor finish and making a waterproof seal between the outlet and floor. The floor must be graded evenly to the shower drain to prevent water escaping out of the shower area.
Design Guidance

17. All heads of underground drainage shall be identified and the pipes extended above ground and vented to atmosphere.
18. Ensure that all vent pipe terminals discharge to atmosphere at such a height and position that foul air does not cause a nuisance or health hazard.
19. All uPVC pipework shall be jointed by solvent welding with allowance for expansion.
20. Kitchen waste systems shall be robust and suitable to receive high temperature discharges and be easy to clean.
21. Sink traps shall be two-piece tubular with 75mm water seal.
22. Flat gradients must be avoided and in particular branch discharge pipes from macerators should be as short as possible.
23. Pipework passing through sensitive areas to be acoustically insulated. Push fit acoustic pipework should be avoided.
24. Upper level plantroom drainage from boilers and hot water generators shall be in a dedicated non-combustible material such as cast iron.
25. Condensate drainage from ACU’s to be in copper or ABS and must be well supported to provide an even gradient. uPVC pipe must NOT be used. The pipework to only discharge into the foul water drainage system via a trapped air break.
26. Radioactive waste to be drained via borosilicate glass pipework
27. All uPVC pipework passing through structure / fire compartments shall utilise surface mounted steel fire collars. The use of concealed intumescent fire wraps are not accepted.
